ACCESSION NR: AT4030807

AUTHOR: Belyayev, G. I.; Smakota, N. F.; Verbitskiy, P. G.; Barinov, Yu. D.

TITLE: On the interaction of borosilicate melts with certain metals and oxides

SOURCE: AN UkrSSR. Institut metallokeramiki i spetsial'nykh splavov.
Poverkhnostnyye yavleniya v rasplavakh i protsessakh poroshkovoy metallurgii
(surface phenomena in liquid metals and processes in powder metallurgy), Kiev,
Izd-vo AN UkrSSR, 1963. 262-272

TOPIC TAGS: borosilicate, oxide, vitreous covering, metal ceramic material,
silicate, steel, sodium borosilicate glass

ABSTRACT: In this paper the authors studied the process of the reaction of steel with sodium borosilicate glasses of different acidity. It was shown that in compositions of metal glass at high temperatures, a chemical reaction of phases occurs which is accompanied by the solution of the metal, the enrichment of the alloy by its oxides, and a separation of gases which leads to the expansion and formation of a foamy structure near the interphase boundary. It was established that the nature of the silicate melt has a considerable effect on the speed of dissolution of the steel samples; the solubility of steel increases with an increase in the alkalinity

Card 1/2

ACCESSION NR: AT4030807

of the glass. The intensity of the expansion of the borosilicate alloy rises with the increase of the glass alkalinity. Metals have a great effect on the expansion. An insignificant expansion of the alloy was observed in the reaction with nickel, copper, and molybdenum; compositions consisting of glass with powdered iron, cobalt, or chromium additives, expand strongly. It was shown that the solubility of the iron oxides decreases with an increase in the acidity of the glass. In pure boron anhydride, ferric oxide practically does not dissolve. Orig. art. has: 11 figures and 1 table.

TITLE: Velocities and attenuation of elastic waves in sedimentary rocks

SOURCE: AN UkrSSR. Mezhdovedomstvennyy geofizicheskiy komitet. Informatsionnyy byulleten', no. 9, 1966. Geofizika i astronomiya, 29-31

TOPIC TAGS: seismic wave, sedimentary rock, elastic wave, longitudinal wave, transverse wave, ultrasonic measurement

ABSTRACT: The author presents a short description of the procedure and results of the study of velocities and attenuation of elastic waves in sedimentary rocks with fillers (distilled water, kerosene, and NaCl solution) under effective loads. The investigation of rock samples was conducted in a special core-holding bomb which permitted the measurement of longitudinal and shear wave velocities at axial and lateral pressures up to 1000 atm, hydrostatic pressure of 300 atm, and temperature up to 90C. The core-holding bomb made it possible to replace pore fluids and to register the volumetric charge of the pore spaces. The measurement was performed by the pulse method at frequencies of 500 kcps. Based on an analysis of the experimental data, it was concluded that attenuation of longitudinal waves decreased with

Card 1/2

ACC NR: AT6032429

increasing effective pressure. The change in attenuation characteristics exhibited an inverse relationship to the change in velocity characteristics. It was also noticed that the attenuation characteristics of longitudinal waves are influenced by the fluid saturation of the sample. The investigation of rock samples made it possible to test ultrasonic measurements under conditions close to those prevailing in situ at depths up to 5 km. [BA]

TITLE: Experimental determination of some factors in electric arc welding

PERIODICAL: Referativnyi zhurnal. Metallurgiya, no. 12, 1961, 22, abstract
12E127 ("Tr. Ufimsk. aviats. in-ta", 1960, no. 5, 101 - 105)

TEXT: The author analyzes some preliminary results of determining the factors of fusion, building-up, and loss by burning and spatter in manual arc welding on d-c of direct polarity, with chalk-coated electrodes. Welding was performed on a CVP-2P(300-2R) type machine. Beads were built-up on 8 - 10 mm thick grade "2" steel specimens. The electrodes were made of CBI (SV1) wire of conventional diameters. Recommendations are given as to investigation methods and determining of optimum welding conditions.

TITLE:

Radiation of loop antenna in an electrically-conducting medium

PERIODICAL:

Akademiya nauk UkrSSR. Dopovidi. no. 9, 1961, 1165-1168

TEXT: The field conditions of geophysical investigations require compact and light equipment. Hence the a.c.-loop antennas are small; the overall loop perimeter is smaller than the wavelength, and the magnitude of the current is the same at all the points of the loop. The length of the equivalent dipole of a single-loop antenna is expressed by formula

$$l_e = \frac{2\pi S}{\lambda}$$

(1)

where S is the loop area. The radiation resistance R_e is expressed

Card 1/6

28691

Radiation of loop ...

S/021/61/000/009/009/012
D274/D304

by

$$R_{\Sigma} = \frac{8}{3} \pi^3 \frac{S^2}{\lambda^4} \rho \quad (2)$$

where ρ is the resistance of the medium. In the frequency range used for a.c.-geophysical surveys, ($f = 0.1-1 \cdot 10^7$ cycles), the surface layer of the earth is a good conductor. If an antenna with

$$l_{e_0} = \frac{2\pi S}{\lambda_0} \quad (4)$$

$$R_{\Sigma_0} = \frac{8}{3} \pi^3 \frac{S^2}{\lambda_0^4} \rho_0 = 320 \pi^4 \frac{S^2}{\lambda_0^4} \quad (5)$$

Card 2/ 6

28691

Radiation of loop ...

S/021/61/000/009/009/012
D274/D304

is carried from air (μ_0, ϵ_0) into a conducting medium, then

$$l_e = \frac{2\pi S}{\lambda} = \frac{2\pi S}{\lambda_0} \sqrt{\frac{g}{2\omega\epsilon_0} \cdot \frac{\mu}{\mu_0}} \quad (6)$$

$$R_\Sigma = \frac{8}{3} \pi^3 \frac{S^2}{\lambda^4} g = \frac{8}{3} \pi^3 \frac{S^2}{\lambda_0^4} \left(\frac{g}{2\omega\epsilon_0} \cdot \frac{\mu}{\mu_0} \right)^2 \cdot \sqrt{\frac{\omega\mu}{g}} \quad (7) \quad \text{H}$$

(g denotes the conductance), and its equivalent length and resistance are increased by

$$m = \frac{l_e}{l_{e_0}} = \sqrt{\frac{g}{2\omega\epsilon_0} \cdot \frac{\mu}{\mu_0}} \quad (8)$$

Card 3/6

Radiation of loop ...

and

28691

S/021/61/000/009/009/012
D274/D304

$$n = \frac{R_E}{R_{E0}} = \left(\frac{R}{2\omega\epsilon_0} \cdot \frac{\mu}{\mu_0} \right)^2 \cdot \frac{\sqrt{\frac{\omega\mu}{R}}}{\sqrt{\frac{\mu_0}{\epsilon_0}}} = \frac{1}{4} \frac{R}{\omega\epsilon_0} \left(\frac{\mu}{\mu_0} \right)^2 \sqrt{\frac{R}{\omega\epsilon_0} \frac{\mu}{\mu_0}} \quad (9) \quad \text{LH}$$

respectively. In this case the power of radiation P_Σ is expressed by

$$P_\Sigma = \frac{R_E I^2}{2} = \frac{\omega^2 \mu^2 S^2 I^2 R}{48\pi} \sqrt{\mu R \omega} = \frac{\omega^2 \mu^2 S^2 I^2 R}{24\pi} \alpha \quad (10)$$

Card 4/6

S/021/61/000/009/009/012
D274/D304

Radiation of loop ...

Further, the depth of survey is calculated for an antenna placed in an infinite conducting medium. The relative increase (with respect to air as a medium) in depth is expressed by

$$\frac{\Delta z}{z_1} = \frac{z_2 - z_1}{z_1} \approx \frac{\ln \frac{H_{02}}{H} - \ln \frac{H_{01}}{H}}{\ln \frac{H_{01}}{H}} = \frac{\ln \frac{H_{02}}{H_{01}}}{\ln \frac{H_{01}}{H}}; \quad (14)$$

$$\frac{\Delta z}{z_1} \approx \frac{\ln m}{\ln \frac{H_{01}}{H}}.$$

where H is the magnetic field-strength. An example is given which shows that if the loop antenna is moved from air into ground to a depth of 1 m., the depth of survey increases by 20% even under most unfavorable conditions. In practice, the increase in depth

Card 5/6

28691

S/021/61/000/009/009/012
D274/D304

Radiation of loop ...

is somewhat lower, as the simplifying assumptions leading to formula (14) do not hold. Thus, a loop antenna of thinly-insulated wire has greater equivalent length, resistance and power if it is carried from air into a conducting medium. This effect increases with decreasing frequency and increasing conductivity and permeability of the medium. The described property of loop antennas might be used in surveys involving surface layers of high conductivity. There are 3 Soviet-bloc references. 41

Compound

PERIODICAL: Izv. Leningr. elektrotekhn. in-ta, 1959, No. 3, pp. 300-302

TEXT: InSb single crystals were grown at a specially developed unit by the Chokhralskiy method in an inert gas atmosphere. The initial In and Sb were subjected to zonal recrystallization purification. The primer extraction was started after a two-hour mixing of the smelt and performed while rotating the crucible. It is necessary to orient the primer corresponding to the 110-plane to avoid the degeneration of individual faces during growing.

PURPOSE: This collection of articles is intended for engineers and technicians of metallurgical and machine-building plants, senior students of schools of higher education, staff members of design bureaus and planning institutes, and scientific research workers.

COVERAGE: The collection contains reports presented at the fifth annual convention devoted to the review of the physicochemical bases of the steelmaking process. These reports deal with problems of the mechanism and kinetics of reactions taking place in the molten metal in steelmaking furnaces. The following are also discussed: problems involved in the production of alloyed steel, the structure of the ingot, the mechanism of solidification, and the converter steelmaking process. The articles contain conclusions drawn from the results of experimental studies, and are accompanied by references of which most are Soviet.

TITLE: Rheological properties of plastic lubricants and rotary resistance of rolling friction bearings at low speeds

SOURCE: AN SSSR. Doklady, v. 172, no. 3, 1967, 572-575

TOPIC TAGS: ball bearing, lubricant property, lubricant viscosity, *elasticity, roller bearing, plastic lubricant, test method*

ABSTRACT: The authors point out that most investigations of the elastic properties, strength, and viscosity of lubricants and their effects on roller bearings do not deal with the rotary resistance at low and very low speeds. They therefore investigated a radial-thrust two-row bearing (type ATsKB2339), using a test setup in which the speed could be varied between 2.5×10^{-4} and 3000 rpm. An electromagnetic clutch afforded breaking of the rotor within 0.1 sec, and special devices were used to apply loads to the inner races of the bearing and to measure the various forces. Sodium (VNIIP-223) and lithium (TsIATIM-201) lubricants were tested. The results indicate that there is a qualitative correspondence between the behavior of various lubricants in rolling friction bearings and in devices with coaxial cylinders at low speeds. At speeds down to ~5 rpm the two lubricants exhibited similar friction resistance, approximately equal to that of dioctylsebacinate oil (which was used for comparison). At low

Card 1/2

UDC: 665.4: 621.822.6

ACC NR: AP7007294

speeds, however, the two plastic lubricants had much higher friction resistance than oil. Furthermore, at a speed below some critical value the friction torque was not constant, but exhibited a jumplike self-oscillation, which varied from sample to sample. The behavior of the friction in the bearing at low speeds depended also on the prior direction of rotation, owing to different orientation-dependent effects at the point of contact between the balls and the races of the bearing. To explain the phenomenon, tests were made of the rheological properties of the lubricants at low shear rates, using a rotary plastoviscosimeter. At low speeds, spontaneous oscillations of the shear stress were observed, owing to reversible spontaneous disintegration and recovery of the structure with a periodicity that depends both on the nature of the lubricant and on the rigidity of the dynamometer. The authors thank G. V. Vinogradov for valuable advice during the discussion of the work. This report was presented by Academician P. A. Rebinder 28 March 1966. Orig. art. has: 2 figures.

TITLE: An Investigation of the Forging of Molten Iron (Issledovaniye zhidkoy shtampovki chuguna)

PERIODICAL: V sb.: Mashinostroitel' Belorussii, Nr 4. Minsk, 1957, pp 29-37

ABSTRACT: A study was made of a process of molten forging (MF) of iron products, process procedures for MF, and the mechanical properties of the parts thus produced. Descriptions are offered of melting furnaces, casting fixtures, and control of temperature and chemical composition of the molten metal. An IZh-50 hydraulic press was employed. In order to pursue further investigation of their mechanical properties, the parts chosen for forging were rods of 10.5, 13.5, and 17.5 mm. The temperature of the iron fluctuated in the 1280-1320°C interval. The die was heated to 320-400°, depending upon the diameter of the rod. It was found that MF without heating of the die yielded impaired results. The pressure of the punch on the cast metal was 12 kg/mm², and it was held down for 3 to 10 seconds. Cracks

Card 1/2

SOV/137-52-9-19032

An Investigation of the Forging of Molten Iron

appeared when lower pressures were employed. Coatings of 8 different compositions were tested for elimination of welding of the iron to the tool. The best results were obtained with a coating consisting of 120 g chalk, 20 g water glass, and 1000 g water. It was established that when the rod is allowed to cool rapidly in air after MF longitudinal cracks 2-3 mm deep often come into being, while fast cooling in the die leads to the appearance of transverse cracks. To avoid this defect, a batch of rods was placed in a furnace having a temperature of 700-800° after extraction from the die and were cooled with the furnace to 350-400°. This resulted in preservation of the initial structure and relieved any stresses in the rod due to uneven cooling. Results of tests of the mechanical properties of cast and forged-iron rods are adduced. The mechanical properties of MF parts were found to be higher than those of cast parts by 25-35% for σ_b , 45-50% for σ_b compr', 65-70% for σ_b creep, 120-150% for ψ , and 18-25% for a_k . In the process of MF, iron of the composition employed becomes chilled throughout. This is removed by a brief subsequent anneal at 940-950° for 10-15 min. The anneal results in the acquisition of the structure of malleable cast iron. The graphite is of the flake type and the metallic base is pearlitic-ferritic. See RZhMet, 1958, Nr 5, abstract 9607. 1. TITLE: Nickel plating by means of the gas phase reaction of Nickel tetracarbonyl vapor

PERIODICAL: Zhurnal prikladnoy khimii, 1970, Vol. 43, No. 1, pp. 110-116 (USSR)

ABSTRACT: The authors developed an installation for nickel plating with vapors of nickel tetracarbonyl (see fig. 1). Fan 1 supplies the gas mixture (nickel tetracarbonyl + CO) to the reactor 2 containing the objects to be plated, heated to a predetermined optimum temperature. Partially exhausted gas goes to the condenser 3 where it is enriched and returned to its original concentration with liquid nickel tetracarbonyl supplied from storage tank 4 through the dosing apparatus 5. The gas goes then through the expansion vessel 6 to the receiver 7 from which the fan 1 recirculates it. The system is slightly pressurized (50-100 mm water) by means of the gas holder 11 to prevent any air intake.

SOV/80-33-1-19-17

The excess pressure due to the large amount of CO liberated on decomposition of nickel tetracarbonyl is reduced by directing a part of the gas to the furnace 12 where it is burned to CO₂ and discharged into the atmosphere. Optima conditions were established, as follows: oxygen content in the gas mixture, 0.4% maximum; temperature, 275 to 285° C at 20 to 25% nickel carbonyl content in the gas mixture; gas velocity around the treated surface, not less than 0.006 m/sec. To assure uniformity of the nickel coating, the direction of the gas flow was reversed every 30 to 60 seconds by means of the valves 8. The thickness of the coating thus obtained varied by + 2 to 3 μ . The coating showed poor adherence to the metal surface; this lack of adherence disappeared after heat treatment under hydrogen at 550-700° C. After such treatment the samples successfully sustained repeated 180° bending. Microphotographic and X-ray investigation showed that the nickel coating has a crystalline β -phase structure with an identity period of 3.517-3.519 Å which is close to the standard

Card 3/5

Nickel Plating by Means of Thermal Decomposition of Nickel Tetracarbonyl Vapors

77510

SOV/80-33-1-197-9

parameter of the Ni cubic face-centered unit cell. The nickel crystal size grew with the concentration of nickel carbonyl in the gaseous phase and varied in the range from 10^{-4} to 10^{-2} cm. The hardness of the heat-treated coating was 240-270, according to Vickers. The porosity was very low, practically nil in coatings of more than 10μ thickness, and their protective properties compared favorably in every respect with those of electroplated ones. The reasons which restrict the wide application of this method are: the toxicity of nickel tetracarbonyl; the difficulties of its transportation over long distances; the necessity of heat treatment of the plated objects; the difficulty of bringing the whole treated surface to a uniform temperature within narrow limits; and the dull appearance of the coating. E. Sh. Ioffe and A. I. Zaslavskiy cooperated in the X-ray investigation; corrosion laboratory tests were made under the supervision of Ye. V. Urnis. There are 7 figures; 1 table; and 16 references, 11 U.S., 5 Soviet. The 5 most recent

Hydrometeorological conditions and thermal balance of Lake Baikal. (Gidrometeorologicheskiy rezhim i teplovoy balans ozera Baykal) Moscow, Izd-vo "Nauka", 1965, 372 p. illus., biblio. (At head of title: Akademiya nauk SSSR. Sibirskoye otdeleniye. Limnologicheskiy institut) Errata slip inserted. 1,000 copies printed.

TOPIC TAGS: hydrometeorology, hydrology, surface water, heat balance, air temperature, moisture measurement, solar radiation absorption, turbulent heat transfer, ice / LAKE BAIKAL

PURPOSE AND COVERAGE: This book presents the normal properties over several years of radiational and thermal balances of the surface of Lake Baikal. It describes processes of heat and moisture exchange with the atmospheric and internal water exchange ranging from the surface of the lake to depths of 200 meters. Also included is an analysis of the mechanism of a series of processes and phenomena which influence the hydrometeorological conditions of Baikal.
